Effect of Particle Addition on Degradation Rate of Methylene Blue in an Ultrasonic Field
超音波を用いたメチレンブルー分解速度に固体粒子がおよぼす影響

1. Introduction

Many organic compounds have been released and appeared as environmental pollutants. Techniques for the degradation of hazardous organic compounds have been investigated. UV light irradiation to TiO₂ photocatalysis is one of the favorite techniques ¹. The positive holes generated by UV light irradiation in the vicinity of the surface of TiO₂ particles react with water to produce OH radicals. However, UV light is screened by TiO₂ particles, so that there is a limit amount of particle addition in which degradation rate increases.

Ultrasound has been found to be an attractive advanced technology for the degradation in water ². In addition, the sonochemical reaction is enhanced by particle addition. Especially, the combination of photocatalysis and ultrasound is considered to enhance the degradation rate. The degradation of phenol by ultrasonic irradiation in the presence of TiO₂ particles has been investigated in complete darkness ³. Sekiguchi and Saita have been investigated the effect of Al₂O₃ particles on the degradation of chlorobenzene in an ultrasonic field ⁴. However, the enhancement mechanism of particle addition has not been investigated well, because ultrasound enhances not only chemical reaction but also mass transfer.

In this study, the ultrasonic degradation of methylene blue was carried out, and the effects of ultrasonic irradiation condition on the degradation rate were investigated. The effects of ultrasonic frequency on improvement of degradation by particle addition was also investigated.

2. Experimental

Fig. 1 shows the experimental apparatus. A stainless steel plate attached with PZT transducer (Honda Electronics Co., Ltd.) was installed in the center of the water bath at the bottom. The ultrasonic frequency was operated at 22.8 kHz, 127 kHz, 490 kHz, 940 kHz and 1640 kHz. The transducers were driven by a power amplifier (1040L, E&J), which in turn was driven by a continuous sinusoidal wave produced using a signal generator (WF1974, NF Corp.). The effective electric power input to the transducer was calculated from the voltage at both ends of the transducer, the current measured using an oscilloscope (TDS3012C, Tektronix Inc.), and a current probe (TCP202, Tektronix Inc.).

The temperature of the water bath was kept constant by a thermostat.

Table 1 shows the experimental conditions for methylene blue degradation. Process variables were defined as follows: ultrasonic frequency (f), ultrasonic output power (P), distance between the ultrasonic transducer and the bottom of the reactor (L₁), distance between the ultrasonic transducer and the level of the water bath (L₂), irradiation time, and amount of particle (TiO₂ or Al₂O₃) addition (w). The volume of the sample solution (V), temperature of the water bath (T), and initial methylene blue concentration (C₀) were kept constant. The diameters of additive particles of TiO₂ and Al₂O₃ were 300 nm and 50 µm, respectively.

Before ultrasonic irradiation, the sample solution and the remaining space in the reactor were deoxygenated with a nitrogen gas flow for 20 min. After deoxygenation, the sample was irradiated with ultrasound under a continuous flow of nitrogen gas (0.1 L/min). After ultrasonic irradiation, the methylene blue concentration ($C$) was determined by measuring the absorbance of the sample at a wavelength of 665 nm using UV-vis spectrometer (Agilent 8453, Agilent Technologies). The determined absorbance was converted to a concentration through the standard curve of methylene blue. Before the analysis, the suspension was centrifuged to remove particles. The ultrasonic power in the reactor was measured by calorimetry5).

The effects of frequency on sonochemical efficiency were also evaluated using $SE_{kl}$ value6).

3. Results and Discussions

Fig. 2 shows the effect of TiO$_2$ concentration on apparent degradation rate constant at $f = 490$ kHz and $P = 8$ W. The apparent degradation rate constant increases with increasing TiO$_2$ concentration. The optimal concentration of TiO$_2$ was 0.25 g/L in the photocatalytic irradiation system, because the UV light was hindered by the excess TiO$_2$ particles7). However, such a phenomenon was not observed in this ultrasonic irradiation system.

![Fig. 2 Effect of TiO$_2$ concentration on apparent degradation rate constant at $f = 490$ kHz and $P = 8$ W](image)

Fig. 3 shows the effect of particle addition on the time dependence of methylene blue concentration at $P = 8$ W and $w = 1.0$ g. The degradation rate of methylene blue was increased by particle addition. The degradation rate was improved by TiO$_2$ particle addition at $f = 490$ kHz. On the other hand, the degradation rate was improved by Al$_2$O$_3$ particle addition at $f = 127$ kHz. The relationship between particle size and resonance diameter is important to enhance the ultrasonic reaction in the presence of particle.

![Fig. 3 Effect of particle addition on time dependence of methylene blue concentration at $P = 8$ W and $w = 1.0$ g: (a) $f = 127$ kHz, (b) $f = 490$ kHz](image)

4. Conclusion

The degradation process of methylene blue was intensified by particle addition, and the degradation rate increased with increasing amount of particle addition. The enhancement of degradation rate by particle addition was influenced by both ultrasonic frequency and type of particle.
